

This website is designed for my girlfriend.

I use the roll over as navigation in the main page. So it gives users a simple and easy-going feeling. This website can be divided into 4 parts, "About Me", "Resume", "Experience" and "Contact". And in Contact part user can interact with this website.

PHP is used to deal with form. When user inputs their information, php code will automatically check their inputs and give different response. If you input the valid e-mail address(using Regular Expression to check), this system will automatically send one email to this email address to confirm.

WOW: I have used roll over effect as navigation and in this way I think my website is more friendly and simpler to users. I also use regular expression to check whether the input email address is valid or not. And if it is valid, php will send an email to this address automatically.
